

Generic pattern unification: a categorical approach

Ambroise Lafont^[0000–0002–9299–641X]

University of Cambridge

Abstract. We provide a generic setting for pattern unification using category theory. The syntax with metavariables is generated by a free monad applied to finite coproducts of representable functors; the most general unifier is computed as a coequaliser in the Kleisli category of this monad. Beyond simply typed second-order syntax, our categorical proof handles unification for linear or (intrinsic) polymorphic syntax such as system F.

Keywords: Unification · Category theory.

1 Introduction

Unification consists in finding the most general unifier of two terms involving metavariables. To be more explicit, a unifier is a substitution that replaces metavariables with terms, potentially involving metavariables, such that the two substituted terms are equal. The most general unifier is the one that uniquely factors any other unifier.

In pattern unification, the arguments of a metavariable are restricted to be distinct variables. In that case, we can design an algorithm that either fails in case there is no unifier, either computes the most general unifier. Roughly, the algorithm recursively inspect the structure of the given pair of terms, until reaching a metavariable application $M(x_1, \dots, x_n)$ at top level. It then performs an *occur-check*, testing whether this metavariable M occurs in the other handside u . If not, it enters a *pruning phase*, and tries to remove all *outbound* variables in u , i.e., variables that are not among x_1, \dots, x_n . It does so by producing a substitution that restricts the arities of the metavariables occurring in u .

The other possible outcome of the occur-check is that M appears in u . In this case, there is no unifier unless M appears at top-level, because the size of substituted terms can never match.

Categorification

In this section, we consider more formally pattern unification for the syntax of pure λ -calculus. This case study allows us to motivate our categorical account of pattern unification.

Consider the category of functors $[\mathbb{F}_m, \text{Set}]$ from \mathbb{F}_m , the category of finite cardinals and injections between them, to the category of sets. A functor $X :$

$\mathbb{F}_m \rightarrow \text{Set}$ can be thought of as assigning to each natural number n a set X_n of expressions with free variables taken in the set $\underline{n} = \{0, \dots, n-1\}$. The action on morphisms of \mathbb{F}_m means that these expressions support injective renamings. Pure λ -calculus is such a functor A satisfying the recursive equation $A_n \cong \underline{n} + A_n \times A_n + A_{n+1}$, where $- + -$ is disjoint union.

In pattern unification, we consider extensions of this syntax with metavariables taking a list of distinct variables as arguments. As an example, let us add a metavariable of arity p . The extended syntax A' now satisfies the recursive equation $A'_n = n + A'_n \times A'_n + A_{n+1} + \text{Inj}(p, n)$, where $\text{Inj}(p, n)$ is the set of injections between the cardinal sets p and n , corresponding a choice of arguments for the metavariable. In other words, $\text{Inj}(p, n)$ is nothing but the set of morphisms between p and n in the category \mathbb{F}_m , which we denote by $\mathbb{F}_m(p, n)$.

Obviously, the functors A and A' satisfy similar recursive equations. Denoting Σ the endofunctor on $[\mathbb{F}_m, \text{Set}]$ mapping F to $I + F \times F + F(- + 1)$, where I is the functor mapping n to \underline{n} , the functor A can be characterised as the initial algebra for Σ , thus satisfying the recursive equation $A \cong \Sigma(A)$, while A' is characterised as the initial algebra for $\Sigma(-) + yp$, where yp is the representable functor $\mathbb{F}_m(p, -) : \mathbb{F}_m \rightarrow \text{Set}$, thus satisfying the recursive equation $A' \cong \Sigma(A') + yp$. In other words, A' is the free Σ -algebra on yp . Denoting T the free Σ -algebra monad, A is $T(0)$ and A' is $T(yp)$. Similarly, if we want to extend the syntax with another metavariable of arity q , then the resulting functor would be $T(yp + yq)$.

In the view to abstracting pattern unification, these observations motivate considering functors categories $[\mathcal{A}, \text{Set}]$, where \mathcal{A} is a small category where all morphisms are monomorphic (to account for the pattern condition enforcing that metavariable arguments are distinct variables), together with an endofunctor Σ on it. Then, the abstract definition of a syntax extended with metavariables is the free Σ -algebra monad T applied to a finite coproduct of representable functors.

To understand how a unification problem is stated in this general setting, let us come back to the example of pure λ -calculus. Consider Kleisli morphisms for the monad T . A morphism $\sigma : yp \rightarrow T(yn)$ is equivalently given (by the Yoneda Lemma) by an element of $T(yn)_p$, that is, a λ -term t potentially involving a metavariable of arity n , with p free variables. Note that this is the necessary data to substitute a metavariable M of arity p : then, $M(x_1, \dots, x_p)$ gets replaced with $t[i \mapsto x_{i+1}]$. Thus, Kleisli morphisms account for metavariable substitution and for term selection. Considering a pair of composable Kleisli morphisms $yp \rightarrow T(yn)$ and $yn \rightarrow T(yq)$, if we interpret the first one as a term $t \in T(yn)_p$ and the second one as a metavariable substitution σ , then, the composition corresponds to the substituted term $t[\sigma]$. Now, a unification problem can be stated as a pair of parallel Kleisli morphisms

$$yp \rightrightarrows T(yq_1 + \dots + yq_n)$$

corresponding to selecting a pair of terms with p free variables and involving metavariables of arity q_1, \dots, q_n . A unifier is nothing but a Kleisli morphism coequalising this pair. The most general unifier, if it exists, is the coequaliser,

in the full subcategory spanned by coproducts of representable presheaves. The main purpose of the pattern unification algorithm consists in constructing this coequaliser, if it exists, which is the case as long as there exists a unifier.

Related work

First-order unification was categorically described in [4, Chapter 9], which basically corresponds to replacing \mathbb{F}_m in the introduction by the terminal category, so that we are working in the category of sets. Pattern unification was introduced in [3], as a particular case of higher-order unification for the simply-typed lambda-calculus, where metavariables are applied to distinct variables. It was categorically rephrased in [6], with concluding hints about how to generalise their work. The present paper can be thought of as an explicit realisation of this generalisation.

Plan of the paper

In Section 2, we present our categorical setting. In Section 3, we state our main result that justifies pattern unification algorithms. Then we describe the construction of the most general unifier, as summarised in Figure 1, starting with the the unification phase (Section 4), the pruning phase (Section 5), the occur-check (Section 6), and finally we justify completeness (Section 7). Applications are presented in Section 8.

General notations

If \mathcal{B} is a category and a and b are two objects, we denote the set of morphisms between a and b by $\text{hom}_{\mathcal{B}}(a, b)$ or $\mathcal{B}(a, b)$.

We denote the identity morphism at an object x by 1_x . We denote by $()$ any initial morphism and by $!$ any terminal morphism.

We denote the coproduct of two objects A and B by $A + B$ and the coproduct of a family of objects $(A_i)_{i \in I}$ by $\coprod_{i \in I} A_i$, and similarly for morphisms.

If $(g_i : A_i \rightarrow B)_{i \in I}$ is a family of arrows, we denote by $[g_i] : \coprod_{i \in I} A_i \rightarrow B$ the induced coproduct pairing. If $f : A \rightarrow B$ and $g : A' \rightarrow B$, we sometimes denote the induced morphism $[f, g] : A + A' \rightarrow B$ by merely f, g . Conversely, if $g : \coprod_{i \in I} A_i \rightarrow B$, we denote by g_i the morphism $A_i \rightarrow \coprod_{i \in I} A_i \rightarrow B$.

Coproduct injections $A_i \rightarrow \coprod_{i \in I} A_i$ are typically denoted by in_i .

Given an adjunction $L \dashv R$ and a morphism $f : A \rightarrow RB$, we denote by $f^* : LA \rightarrow B$ its transpose, and similarly, if $g : LA \rightarrow B$, then $g^* : A \rightarrow RB$.

Let T be a monad on a category \mathcal{B} . We denote its unit by η , and its Kleisli category by Kl_T : the objects are the same as those of \mathcal{B} , and a Kleisli morphism from A to B is a morphism $A \rightarrow TB$ in \mathcal{B} . Any Kleisli morphism $f : A \rightarrow TB$ induces a morphism $f^* : TA \rightarrow TB$. We denote the Kleisli composition of $f : A \rightarrow TB$ and $g : TB \rightarrow T\Gamma$ by $f[g] = g^* \circ f$. We denote by \mathcal{L} the left adjoint $\mathcal{L} : \mathcal{B} \rightarrow Kl_T$ which is the identity on objects and postcomposes any morphism $A \rightarrow B$ by $\eta_B : B \rightarrow TB$.

Unification phase

- Structural rules (Section 4)

$$\frac{}{\overline{\Gamma \vdash () = () \Rightarrow 1_\Gamma \dashv \Gamma}} \quad \frac{}{\overline{\perp \vdash t = u \Rightarrow ! \dashv \perp}}$$

$$\frac{\Gamma \vdash t_1 = u_1 \Rightarrow \sigma_1 \dashv \Delta_1 \quad \Delta_1 \vdash t_2[\sigma_1] = u_2[\sigma_1] \Rightarrow \sigma_2 \dashv \Delta_2}{\Gamma \vdash t_1, t_2 = u_1, u_2 \Rightarrow \sigma_1[\sigma_2] \dashv \Delta_2} \text{U-SPLIT}$$

- Rigid-rigid (Section 4.1)

$$\frac{\Gamma \vdash f = g \Rightarrow \sigma \dashv \Delta}{\Gamma \vdash o(f; s) = o(g; s) \Rightarrow \sigma \dashv \Delta}$$

$$\frac{o \neq o'}{\Gamma \vdash o(f; s) = o'(f'; s') \Rightarrow ! \dashv \perp} \quad \frac{s \neq s'}{\Gamma \vdash o(f; s) = o(f'; s') \Rightarrow ! \dashv \perp}$$

- Flex-*, no cycle (Section 4.4)

$$\frac{u|_\Gamma = \underline{u'} \quad \Gamma \vdash u' :> M(f) \Rightarrow v; \sigma \dashv \Delta}{\Gamma, M : b \vdash M(f) = u \Rightarrow \sigma, M \mapsto v \dashv \Delta} + \text{symmetric rule}$$

- Flex-Rigid, cyclic (Section 4.2)

$$\frac{u = o(g; s) \quad u|_\Gamma = !}{\Gamma, M : b \vdash M(f) = u \Rightarrow ! \dashv \perp} + \text{symmetric rule}$$

- Flex-Flex, same (Section 4.3)

$$\frac{b \vdash f =_{\mathcal{O}} g \Rightarrow h \dashv c}{\Gamma, M : b \vdash M(f) = M(g) \Rightarrow M \mapsto M'(h) \dashv \Gamma, M' : c}$$

Pruning phase

- Structural rules (Section 5)

$$\frac{}{\overline{\Gamma \vdash () :> () \Rightarrow (); 1_\Gamma \dashv \Gamma}} \quad \frac{}{\overline{\perp \vdash t :> f \Rightarrow !; ! \dashv \perp}}$$

$$\frac{\Gamma \vdash g_1 :> f_1 \Rightarrow u_1; \sigma_1 \dashv \Delta_1 \quad \Delta_1 \vdash g_2 :> f_2[\sigma_1] \Rightarrow u_2; \sigma_2 \dashv \Delta_2}{\Gamma \vdash g_1, g_2 :> f_1 + f_2 \Rightarrow u_1[\sigma_2], u_2; \sigma_1[\sigma_2] \dashv \Delta_2} \text{P-SPLIT}$$

- Rigid (Section 5.1)

$$\frac{s|_f \Rightarrow !}{\Gamma \vdash o(g; s) :> N(f) \Rightarrow !; ! \dashv \perp} \quad \frac{\Gamma \vdash g :> \mathcal{L}f^o \Rightarrow u; \sigma \dashv \Delta \quad s|_f \Rightarrow \underline{s'}}{\Gamma \vdash o(g; s) :> N(f) \Rightarrow o(u; s'); \sigma \dashv \Delta}$$

- Flex (Section 5.2)

$$\frac{c \vdash_{\mathcal{O}} g :> f \Rightarrow g'; f' \dashv d}{\Gamma, M : c \vdash M(g) :> N(f) \Rightarrow M'(g'); M \mapsto M'(f') \dashv \Gamma, M' : d}$$

Fig. 1. Summary of the rules

2 General setting

2.1 Base category

We work in a full subcategory \mathcal{C} of functors $\mathcal{A} \rightarrow \mathbf{Set}$, namely, those preserving finite connected limits, where \mathcal{A} is a small category in which all morphisms are monomorphisms and has finite connected limits.

Example 1. The example of the introduction consider $\mathcal{A} = \mathbb{F}_m$ the category of finite cardinals and injections. Note that \mathcal{C} is the category of nominal sets.

Remark 1. An object of \mathcal{A} is intuitively a metavariable arity, or a ground context. The argument of a metavariable $M : a$ living in a ground context a' is a morphism $a \rightarrow a'$. In the previous example, a metavariable $M : n$ living in a context $m \in \mathbb{N}$ takes as argument a choice of distinct variables $x_1, \dots, x_n \in \{0, \dots, m-1\}$.

Remark 2. The restriction of the monad T to functors preserving finite connected limits is used to justify computation of a new arity. Consider indeed the unification problem $M(x, y) = M(y, x)$, in the example of pure λ -calculus, as in the introduction. We can design a functor P that does not preserve finite connected colimits such that $T(P)$ is the syntax extended with a binary operation $M'(-, -)$ such that $M'(x, y) = M'(y, x)$. Then, the most general unifier, computed in the unrestricted Kleisli category of T , replaces M with M' , while it replaces M with a constant metavariable when computed in the Kleisli category restricted to \mathcal{C} .

The Yoneda embedding $\mathcal{A}^{op} \rightarrow [\mathcal{A}, \mathbf{Set}]$ factors through $\mathcal{C} \rightarrow [\mathcal{A}, \mathbf{Set}]$. We denote the fully faithful embedding as $\mathcal{D} \xrightarrow{K} \mathcal{C}$. A useful lemma that we will exploit is the following:

Lemma 1. *\mathcal{C} is closed under limits, coproducts, and filtered colimits.*

In this rest of this section, we abstract this situation by listing a number of properties that we will use in the following to describe the main unification phase.

Property 1. $K : \mathcal{D} \rightarrow \mathcal{C}$ is fully faithful.

Property 2. \mathcal{C} is cocomplete.

Notation 21. We denote by $\mathcal{D}^+ \xrightarrow{K^+} \mathcal{C}$ the full subcategory of \mathcal{C} consisting of finite coproducts of objects of \mathcal{D} .

Remark 3. \mathcal{D}^+ is equivalent to the category of finite families of objects of \mathcal{A} . Thinking of objects of \mathcal{A} as metavariable arities (Remark 1), \mathcal{D}^+ can be thought of as the category of metavariable contexts and *renamings*.

We now introduce a notation for metavariable contexts, as objects of \mathcal{D}^+ .

Notation 22. The context $M : a_M, N : a_N, \dots$ denotes the object $\coprod_{i \in \{M, N, \dots\}} K a_i \in \mathcal{D}^+$.

We will be interested in coequalisers in the Kleisli category restricted to \mathcal{D}^+ .

Property 3. \mathcal{D} has finite connected colimits and K preserves them.

Property 4. Given any morphism $f : a \rightarrow b$ in \mathcal{D} , the morphism Kf is epimorphic.

Property 5. Coproduct injections $A_i \rightarrow \coprod_j A_j$ in \mathcal{C} are monomorphisms.

Property 6. For each $d \in \mathcal{D}$, the object Kd is connected, i.e., any morphism $Kd \rightarrow \coprod_i A_i$ factors through exactly one coproduct injection $A_j \rightarrow \coprod_i A_i$.

2.2 The endofunctor for syntax

We assume given an endofunctor F on $[\mathcal{A}, \text{Set}]$ defined by

$$F(X) = \coprod_{o \in O} \prod_{j \in J_o} X \circ L_{o,j} \times S_o,$$

for some set O , where, for each $o \in O$,

- $S_o \in \mathcal{C}$;
- J_o is a finite set;
- for each $j \in J_o$, $L_{o,j}$ is an endofunctor on \mathcal{A} preserving finite connected limits.

Remark 4. S_o is, for instance, the variable presheaf (in this case, J_o is empty) or a type flag (in the simply-typed case).

Example 2. In the example of the introduction, the endofunctor on $[\mathbb{F}_m, \text{Set}]$ specifying the λ -calculus is $F(X) = I + X \times X + X \circ (- + 1)$, where I is the representable presheaf $y1$.

Lemma 2. F is finitary and restricts as an endofunctor on \mathcal{C} .

Corollary 1. F generates a free monad that restricts to a monad T on \mathcal{C} . Moreover, TX is the initial algebra of $Z \mapsto X + FZ$, as an endofunctor on \mathcal{C} .

Remark 5. As anticipated in Remark 2, it is crucial to consider the monad T restricted to \mathcal{C} .

We now abstract this situation by stating the properties that we will need.

Notation 23. Given an index $o \in O$, and $a \in \mathcal{D}$, we denote $\prod_{j \in J_o} K L_{o,j} a$ by a^o . Given $f : a \rightarrow b$, we denote the induced morphism $a^o \rightarrow b^o$ by f^o .

Property 7. A morphism $Ka \rightarrow FX$ is equivalently given by an index $o \in O$, a morphism $s : Ka \rightarrow S_o$, and a morphism $f : a^o \rightarrow X$.

Notation 24. Given an index $o \in O$, a morphism $s : Ka \rightarrow S_o$, and $f : a^o \rightarrow TX$, we denote the induced morphism

$$Ka \rightarrow FTX \hookrightarrow TX$$

by $o(f; s)$, where the first morphism $Ka \rightarrow FTX$ is induced by Property 7.

Let $\Gamma = M_1 : a_1, \dots, M_n : a_n \in \mathcal{D}^+$, following Notation 22.

Given $f \in \text{hom}_{\mathcal{D}}(a, a_i)$, we denote the morphism

$$Ka \rightarrow Ka_i \hookrightarrow \Gamma \xrightarrow{\eta} T(\Gamma)$$

by $M_i(f)$.

Property 8. Let $\Gamma = M_1 : a_1, \dots, M_n : a_n \in \mathcal{D}^+$. Then, any morphism $u : Ka \rightarrow T\Gamma$ is one of the two mutually exclusive following possibilities:

- $M_i(f)$ for some unique i and $f : a \rightarrow a_i$,
- $o(f; s)$ for some unique $o \in O$, $f : a^o \rightarrow T\Gamma$ and $s : Ka \rightarrow S_o$.

We say that u is *flexible (flex)* in the first case and *rigid* in the other case.

Lemma 3. Let $\Gamma = M_1 : a_1, \dots, M_n : a_n \in \mathcal{D}^+$ and $g : \Gamma \rightarrow T\Delta$. Then, for any $o \in O$, $f : a^o \rightarrow T\Gamma$ and $s : Ka \rightarrow S_o$, we have $o(f; s)[g] = o(f[g]; s)$, and for any $1 \leq i \leq n$, $x : b \rightarrow a_i$, we have $M_i(x)[g] = g_i \circ Kx$.

Moreover, for any $u : b \rightarrow a$,

$$o(f; s) \circ Ku = o(f \circ u^o; s \circ Ku)$$

We end this section by introducing notations for Kleisli morphisms.

Notation 25. Let Γ and Δ be contexts and $a \in \mathcal{D}$. Any $t : Ka \rightarrow T(\Gamma + \Delta)$ induces a Kleisli morphism $\Gamma, M : a \rightarrow T(\Gamma + \Delta)$ that we denote by $M \mapsto t$.

3 Main result

The main point of pattern unification is that a coequaliser diagram in Kl_T selecting objects in \mathcal{D}^+ either has no unifier, either has a colimiting cocone. Working with this logical disjunction is slightly inconvenient; we rephrase it in terms of a true coequaliser by freely adding a terminal object.

Definition 1. Given a category \mathcal{B} , let \mathcal{B}^* be \mathcal{B} extended freely with a terminal object.

Adding a terminal object results in adding a terminal cocone to all diagrams. As a consequence, we have the following lemma.

Lemma 4. Let J be a diagram in a category \mathcal{B} . The following are equivalent:

1. J has a colimit as long as there exists a cocone;
2. J has a colimit in \mathcal{B}^* .

This lemma allows us to work with true coequalisers in Kl_T^* . The following result is also useful.

Lemma 5. *Given a category \mathcal{B} , the canonical embedding functor $\mathcal{B} \rightarrow \mathcal{B}^*$ creates colimits.*

This has the following useful consequences:

1. whenever the colimit in Kl_T^* is not the terminal object, it is also a colimit in Kl_T ;
2. existing colimits in Kl_T are also colimits in Kl_T^* ;
3. in particular, coproducts in Kl_T (which are computed in \mathcal{C}) are also coproducts in Kl_T^* .

Notation 31. *We denote by \perp the terminal object. Recall that $!$ denote any terminal morphism.*

Here is our main result.

Theorem 1. *Let $Kl_{\mathcal{D}^+}^*$ be the full subcategory of Kl_T^* consisting of objects of $\mathcal{D}^+ \cup \{\perp\}$. Then, $Kl_{\mathcal{D}^+}^*$ has coequalisers and the inclusion $Kl_{\mathcal{D}^+}^* \rightarrow Kl_T^*$ preserves them.*

In other words, for any coequaliser diagram $A \rightrightarrows TB$ in Kl_T where A and B are in \mathcal{D}^+ , either there is no cocone, either there is a coequaliser $B \rightarrow TC$, with $C \in \mathcal{D}^+$.

4 Unification phase

In this section, we describe the main unification phase, which relies on the pruning phase, as we shall see. The goal is to compute a coequaliser in Kl_T^* .

Notation 41. *We denote a coequaliser $A \xrightarrow[t]{t} B - \overset{\sigma}{\succ} C$ in a category \mathcal{B} by $B \vdash t =_{\mathcal{B}} u \Rightarrow \sigma \dashv C$, sometimes even omitting \mathcal{B} .*

The intuition behind this notation is that the symbol \Rightarrow separates the input and the output of the algorithm, that we are going to describe with inductive rules. In fact, we will mainly consider coequalisers $\coprod_i Ka_i \xrightarrow[t]{t} \Gamma - \overset{\sigma}{\succ} \Delta$ (denoted by $\Gamma \vdash t =_{Kl_T} u \Rightarrow \sigma \dashv \Delta$) where Γ and Δ are in $\mathcal{D}^+ \cup \{\perp\}$.

Let us start with simple cases:

- when $\Gamma = \perp$, the coequaliser is the terminal cocone, i.e., $\perp \vdash t = u \Rightarrow ! \dashv \perp$ holds;
- when the coproduct is empty, the coequaliser is just Γ , i.e., $\Gamma \vdash () = () \Rightarrow 1_\Gamma \dashv \Gamma$ holds.

Furthermore, when the coproduct is neither empty nor a singleton, the coequaliser can be decomposed thanks to the following rule:

$$\frac{\Gamma \vdash t_1 = u_1 \Rightarrow \sigma_1 \dashv \Delta_1 \quad \Delta_1 \vdash t_2[\sigma_1] = u_2[\sigma_1] \Rightarrow \sigma_2 \dashv \Delta_2}{\Gamma \vdash t_1, t_2 = u_1, u_2 \Rightarrow \sigma_1[\sigma_2] \dashv \Delta_2} \text{U-SPLIT} \quad (1)$$

This is justified by a general stepwise construction of coequalisers:

Lemma 6 (Theorem 9, [4]). *In any category, if the first two diagrams below are coequalisers, then the last one as well*

$$\begin{array}{ccc} A_1 & \xrightarrow[f'_1]{f_1} & B \dashrightarrow C \\ & & \\ A_2 & \begin{array}{c} \xrightarrow{f_2} B \\ \xrightarrow{f'_2} B \end{array} & \begin{array}{c} B \xrightarrow{u} C \\ B \xrightarrow{u} C \end{array} \dashrightarrow D \end{array}$$

$$A_1 + A_2 \begin{array}{c} \xrightarrow{f_1, f_2} B \\ \xrightarrow{f'_1, f'_2} B \end{array} \dashrightarrow D$$

What remains to be addressed is the case where the coproduct is a singleton and $\Gamma = \coprod_j Kb_j$, that is, a coequaliser diagram

$$Ka \begin{array}{c} \xrightarrow{t} T\Gamma \\ \xrightarrow{u} T\Gamma \end{array}$$

By Lemma 8, $t, u : Ka \rightarrow T\Gamma$ are either rigid or flexible. In the next subsections, we discuss all the different mutually exclusive situations (up to symmetry): rigid-rigid (Section 4.1), *cyclic* flexible-rigid (Section 4.2), in the involved metavariable occurs in the other hand side, cyclic flex-flex (Section 4.3), and finally, non-cyclic flex-* (Section 4.4).

4.1 Rigid-rigid

Here we are in the situation where the parallel morphisms $t, u : Ka \rightarrow T\Gamma$ are $o(f; s)$ and $o'(f'; s')$ for some $o, o' \in O$, morphisms $f : a^o \rightarrow T\Gamma$, $f' : a^{o'} \rightarrow T\Gamma$, and morphisms $s : Ka \rightarrow S_o$ and $s' : Ka \rightarrow S_{o'}$.

Assume given a unifier, i.e., a Kleisli morphism $\sigma : \Gamma \rightarrow T\Delta$ such that $t[\sigma] = u[\sigma]$. By Lemma 3, this means that $o(f[\sigma]; s) = o'(f'[\sigma]; s')$. By Lemma 8, this implies that $o = o'$, $f[\sigma] = f'[\sigma]$, and $s = s'$.

Therefore, we get the following failing rules

$$\frac{o \neq o'}{\Gamma \vdash o(f; s) = o'(f'; s') \Rightarrow ! \dashv \perp} \quad \frac{s \neq s'}{\Gamma \vdash o(f; s) = o(f'; s') \Rightarrow ! \dashv \perp}$$

We now assume $o = o'$ and $s = s'$. Then, σ unifies t and u if and only if it unifies f and f' . This induces an isomorphism between the category of unifiers (i.e., cocones) for t and u and the category of unifiers for f and g . We therefore get the rule

$$\frac{\Gamma \vdash f = g \Rightarrow \sigma \dashv \Delta}{\Gamma \vdash o(f; s) = o(g; s) \Rightarrow \sigma \dashv \Delta} \quad (2)$$

4.2 Flex-rigid, cyclic

In Section 6, we show that in this situation, there is no unifier, justifying the rule

$$\frac{T\Gamma \xrightarrow{Tin_\Gamma} T(\Gamma, M : b) \text{ does not factor } g : a^o \rightarrow T(\Gamma, M : b)}{\Gamma, M : b \vdash M(f) = o(g; s) \Rightarrow ! \dashv \perp} \quad (3)$$

Let us make this rule more effective.

Lemma 7. *There is a morphism $m_{\Gamma; b} : T(\Gamma, M : b) \rightarrow T\Gamma + 1$ such that the following square commutes and is a pullback.*

$$\begin{array}{ccc} T\Gamma & \xrightarrow{Tin_\Gamma} & T(\Gamma, M : b) \\ \parallel & & \downarrow m_{\Gamma; b} \\ T\Gamma & \xrightarrow{in_1} & T\Gamma + 1 \end{array}$$

Proof. The proof consists in equipping $T\Gamma + 1$ with an adequate F -algebra. Considering the embedding $\Gamma, M : b \xrightarrow{\eta^+!} T\Gamma + 1$, we then get the desired morphism by universal property of $T(\Gamma, M : b)$ as a free F -algebra.

Notation 42. *Given $u : Ka \rightarrow T(\Gamma, M : b)$, we denote $m_{\Gamma; b} \circ u$ by $u|_\Gamma$. Moreover, we denote the morphism $Ka \xrightarrow{!} 1 \xrightarrow{in_2} T\Gamma + 1$ by merely $!$ and for any $u' : Ka \rightarrow T\Gamma$, we denote $in_1 \circ u' : Ka \rightarrow T\Gamma + 1$ by \underline{u}' .*

Corollary 2. *A morphism $u : Ka \rightarrow T(\Gamma, M : b)$ factors as $Ka \xrightarrow{u'} T\Gamma \hookrightarrow T(\Gamma, M : b)$ if and only if $u|_\Gamma = \underline{u}'$.*

Therefore, we can rephrase Rule 3 as follows.

$$\frac{u = o(g; s) \quad u|_\Gamma = !}{\Gamma, M : b \vdash M(f) = u \Rightarrow ! \dashv \perp}$$

4.3 Flex-Flex, same metavariable

Here we want to unify $M(f)$ and $M(g)$, with $f, g \in \text{hom}_{\mathcal{D}}(a, b)$, that is, we want to coequalise, in Kl_T^* , the following morphisms

$$\begin{array}{ccccc}
& & Kb & \xrightarrow{\eta} & TKb \\
& \nearrow^{Kf} & & & \searrow^{Tin_M} \\
Ka & & & & T(\dots, M : b) \\
& \searrow_{Kg} & & & \nearrow_{Tin_M} \\
& & Kb & \xrightarrow[\eta]{} & TKb
\end{array}$$

We exploit the following lemma in Kl_T , with $u = \mathcal{L}Kf$ and $v = \mathcal{L}Kg$.

Lemma 8. *In any category, if the below left diagram is a coequaliser, then so is the below right diagram.*

$$\begin{array}{ccc}
& & B \\
& \nearrow^u & \searrow^{in_B} \\
A & \xrightarrow[u]{u} B & \xrightarrow{h+1_D} C+D \\
& \searrow_v & \nearrow_{in_B} \\
& & B
\end{array}$$

Therefore, it is enough to compute the coequaliser of $\mathcal{L}Kf$ and $\mathcal{L}Kg$. Since \mathcal{L} is left adjoint (and thus preserves coequalisers) and K preserves coequalisers (Property 3), we finally get the rule

$$\frac{b \vdash f =_{\mathcal{D}} g \Rightarrow h \dashv c}{\Gamma, M : b \vdash M(f) = M(g) \Rightarrow M \mapsto M'(h) \dashv \Gamma, M' : c}$$

Note that such a coequaliser always exists by Property 3.

4.4 Flex-*, no cycle

In this section, we consider a coequaliser diagram $Ka \xrightarrow[u]{t} T(\Gamma, M : b)$ such that $t = M(f)$ for some $f : a \rightarrow b$, and u factors as $Ka \xrightarrow{u'} T\Gamma \hookrightarrow T(\Gamma, M : b)$.

We exploit the following general lemma with $x = \mathcal{L}Kf$ and $y = u'$.

Lemma 9. *In any category, if the below left diagram is a pushout, then the below right diagram is a coequaliser.*

$$\begin{array}{ccc}
A & \xrightarrow{x} & B \\
y \downarrow & & \downarrow u \\
C & \xrightarrow[v]{} & D
\end{array}
\quad
\begin{array}{ccc}
& & B \\
& \nearrow^x & \searrow^{in_1} \\
A & & B + C \xrightarrow[u,v]{} D \\
& \searrow_y & \nearrow_{in_2} \\
& & C
\end{array}$$

Therefore, it is enough to compute the pushout

$$\begin{array}{ccc} Ka & \xrightarrow{\mathcal{L}Kf} & Kb \\ u' \downarrow & & \downarrow v \\ \Gamma & \xrightarrow[-\sigma]{} & \Delta \end{array}$$

As we will see in Section 5, this is expressed by the statement $\Gamma \vdash u' :> f \Rightarrow v; \sigma \dashv \Delta$. Therefore, we have the rule

$$\frac{\Gamma \vdash u' :> f \Rightarrow v; \sigma \dashv \Delta \quad u = \text{Tin}_\Gamma \circ u'}{\Gamma, M : b \vdash M(f) = u \Rightarrow \sigma, M \mapsto v \dashv \Delta}$$

which we rephrase using Corollary 2 as

$$\frac{u|_\Gamma = \underline{u'} \quad \Gamma \vdash u' :> M(f) \Rightarrow v; \sigma \dashv \Delta}{\Gamma, M : b \vdash M(f) = u \Rightarrow \sigma, M \mapsto v \dashv \Delta}$$

5 Pruning phase

The pruning phase corresponds to computing a pushout diagram in Kl_T^* where one branch is a finite coproduct of free morphisms.

Notation 51. We denote a pushout

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ g \downarrow & & \downarrow u \\ C & \xrightarrow[-\sigma]{} & D \end{array}$$

in a category \mathcal{B} by $B \vdash_{\mathcal{B}} g :> f \Rightarrow u; \sigma \dashv C$, sometimes even omitting \mathcal{B} .

In fact, we will mainly consider pushouts

$$\begin{array}{ccc} \coprod_i Ka_i & \xrightarrow{\coprod_i \mathcal{L}Kf_i = \mathcal{L} \coprod_i KF_i} & \coprod_i Kb_i \\ g \downarrow & & \downarrow u \\ \Gamma & \xrightarrow[-\sigma]{} & \Delta \end{array}$$

denoted by $\Gamma \vdash_{Kl_T^*} g :> \coprod_i \mathcal{L}Kf_i \Rightarrow u; \sigma$ where Γ and Δ are in $\mathcal{D}^+ \cup \{\perp\}$.

Remark 6. For the intuition behind the notation and the relation to the so-called pruning process, consider the case of λ -calculus, as in the introduction. A span $\Gamma \xleftarrow{g} Kn \xrightarrow{\mathcal{L}Kf} Km$ corresponds to a term in $t \in T\Gamma_n$ and a choice of distinct m variables in $\{0, \dots, n-1\}$, that is, an injection $f : m \rightarrow n$. The pushout, if it exists, consists in “coercing” (hence the symbol $:>$) the term t to live in $T\Gamma_m$, by restricting the arity of the metavariables according to $\sigma : \Gamma \rightarrow T\Delta$. The resulting term $u \in \text{hom}(Kn, T\Delta) \cong T\Delta_n$ is t but living in the “smaller” context $\{0, \dots, m-1\}$ in the restricted metavariable context Δ .

Remark 7. A cocone consists in morphisms $\coprod_i Kb_i \xrightarrow{u} T\Delta \xleftarrow{\sigma} \Gamma$ such that $g[\sigma] = u \circ \coprod_i \mathcal{L}Kf_i$, i.e., for all $i \in I$, we have $g_i[\sigma] = u_i \circ Kf_i$.

The simplest case is when the coproduct is empty: then, the pushout is Γ . Another simple case is when $\Gamma = \perp$. Then, the pushout is the terminal cocone. Therefore, we have the rules

$$\overline{\Gamma \vdash () :> () \Rightarrow (); 1_\Gamma \dashv \Gamma} \quad \overline{\perp \vdash t :> f \Rightarrow !; ! \dashv \perp}$$

The pushout can be decomposed into smaller components, thanks to the following lemma.

Lemma 10. *In any category, if the first two diagrams below are pushouts, then the last one as well*

$$\begin{array}{ccc} \begin{array}{ccc} A & \xrightarrow{f_1} & A' \\ g_1 \downarrow & & \downarrow u_1 \\ X & \dashrightarrow_{\sigma_1} & Z \end{array} & \begin{array}{ccc} B & \xrightarrow{f_2} & B' \\ g_2 \downarrow & & \downarrow u_2 \\ X & & Z \\ \sigma_1 \downarrow & & \downarrow \\ Z & \dashrightarrow_{\sigma_2} & Z' \end{array} & \begin{array}{ccc} A + B & \xrightarrow{f_1 + f_2} & A' + B' \\ [g_1, g_2] \downarrow & & \downarrow [\sigma_2 \circ u_1, u_2] \\ X & \dashrightarrow_{\sigma_2 \circ \sigma_1} & Z' \end{array} \end{array}$$

Thus we have the following rule.

$$\frac{\Gamma \vdash g_1 :> f_1 \Rightarrow u_1; \sigma_1 \dashv \Delta_1 \quad \Delta_1 \vdash g_2 :> f_2[\sigma_1] \Rightarrow u_2; \sigma_2 \dashv \Delta_2}{\Gamma \vdash g_1, g_2 :> f_1 + f_2 \Rightarrow u_1[\sigma_2], u_2; \sigma_1[\sigma_2] \dashv \Delta_2} \text{P-SPLIT} \quad (4)$$

We can focus on the case where the coproduct is the singleton (since we focus on finite coproducts of elements of \mathcal{D}) and $\Gamma \neq \perp$. Thus, we want to compute a pushout

$$\begin{array}{ccc} Ka & \xrightarrow{N(f)} & T(N : b) \\ \downarrow & & \\ T\Gamma & & \end{array}$$

By Lemma 8, the left vertical morphism $Ka \rightarrow T\Gamma$ is one of the two following possibilities, investigated separately in the following subsections:

- $M(g)$ for some $g : a \rightarrow c$, where $\Gamma = \dots, M : c$
- $o(g; s)$ for some $o \in O$, $g : a^o \rightarrow T\Gamma$, and $s : Ka \rightarrow S_o$.

5.1 Rigid

We want to compute the pushout

$$\begin{array}{ccc}
Ka & \xrightarrow{N(f)} & N : b \\
\downarrow o(g;s) & & \\
\Gamma & &
\end{array}$$

where $g : a^o \rightarrow T\Gamma$ and $s : Ka \rightarrow S_o$.

By Remark 7, a cocone in Kl_T is given by an object Δ with morphisms $Kb \xrightarrow{u} T\Delta \xleftarrow{\sigma} \Gamma$ such that $o(g;s)[\sigma] = u \circ Kf$. By Lemma 3, this means that $o(g[\sigma];s) = u \circ Kf$. Now, by Lemma 8, u is either some $M'(f')$ or $o'(g';s')$, with $g' : b^o \rightarrow T\Delta$ and $s' : Kb \rightarrow S_{o'}$. But in the first case, $u \circ Kf = M'(f') \circ Kf = M'(f' \circ f)$ so it cannot equal $o(g[\sigma];s)$, by Lemma 8. So we are in the second case, and again by Lemma 8, $o = o'$, $g[\sigma] = g' \circ f^o$ and $s = s' \circ Kf$. Note that such a s' is unique because Kf is epimorphic.

Before stating the rules that these considerations imply, let us introduce some notations.

Notation 52. Given $f \in \text{hom}_{\mathcal{D}}(a,b)$ and $s : Ka \rightarrow S_o$, we write $s|_f \Rightarrow !$ to mean that Kf does not factor s . Otherwise, if $s = s' \circ Kf$, then we write $s|_f \Rightarrow \underline{s'}$.

Therefore we get the rules

$$\frac{s|_f \Rightarrow !}{\Gamma \vdash o(g;s) :> N(f) \Rightarrow !; ! \dashv \perp} \quad (5)$$

$$\frac{\Gamma \vdash g :> \mathcal{L}f^o \Rightarrow u; \sigma \dashv \Delta \quad s|_f \Rightarrow \underline{s'}}{\Gamma \vdash o(g;s) :> N(f) \Rightarrow o(u;s'); \sigma \dashv \Delta} \quad (6)$$

5.2 Flex

Here, we are in the situation where we want to compute the pushout of free morphisms in Kl_T

$$\begin{array}{ccc}
Ka & \xrightarrow{N(f)} & N : b \\
\downarrow M(g) & & \\
\Gamma, M : c & &
\end{array}$$

Note that $N(f) = \mathcal{L}Kf$ while the left vertical morphism $M(g)$ is equal to the composition (in Kl_T) $Ka \xrightarrow{\mathcal{L}Kg} M : c \xrightarrow{\text{in}_M} (\Gamma, M : c)$. Thanks to the following lemma, it is enough to compute the pushout of $\mathcal{L}Kf$ and $\mathcal{L}Kg$.

Lemma 11. *In any category, if the diagram below left is a pushout, then so is the right one.*

$$\begin{array}{ccc}
A & \xrightarrow{f} & B \\
g \downarrow & & \downarrow u \\
X & \xrightarrow{\sigma} & Z
\end{array}
\qquad
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
g \downarrow & & \downarrow u \\
X & & Z \\
in_1 \downarrow & & \downarrow in_1 \\
X + Y & \xrightarrow{\sigma+Y} & Z + Y
\end{array}$$

Since \mathcal{L} is left adjoint (and thus preserves coequalisers) and K preserves pushouts (Property 3), the pushout can be computed in \mathcal{D} . Therefore, we get the rule

$$\frac{c \vdash_{\mathcal{D}} g :> f \Rightarrow g'; f' \dashv d}{\Gamma, M : c \vdash M(g) :> N(f) \Rightarrow M'(g'); M \mapsto M'(f') \dashv \Gamma, M' : d}$$

6 Occur-check

The occur-check allows to jump from the main unification phase (Section 4) to the pruning phase (Section 5), whenever the metavariable appearing at the top-level of the l.h.s does not appear in the r.h.s. This section is devoted to the proof that if there is a unifier, then the metavariable does not appear on the r.h.s, either it appears at top-level (see Corollary 4). The basic intuition is that $t = u[M \mapsto t]$ is impossible if M appears deep in u because the sizes of both hand sides can never match. To make this statement precise, we need some recursive definitions and properties of size, that can be categorically justified by exploiting the universal property of TX as the free F -algebra on X .

Definition 2. The size $|t| \in \mathbb{N}$ of a morphism $t : Ka \rightarrow T\Gamma$ is recursively defined by

$$|M(f)| = 0 \text{ and } |o(g; s)| = 1 + |g|, \text{ with } |g| = \sum_i g_i, \text{ for any } g : \coprod_i Ka_i \rightarrow T\Gamma.$$

Definition 3. For each morphism $t : Ka \rightarrow T(\Gamma, M : b)$ we define $|t|_M$ recursively as follows

$$|N(f)|_M = 0 \text{ if } N \neq M \qquad |M(f)|_M = 1 \qquad |o(g; s)|_M = |g|_M$$

with a similar convention as above for $|g|$.

Lemma 12. For any $t : Ka \rightarrow T(\Gamma, M : b)$, if $|t|_M = 0$, then $T\Gamma \hookrightarrow T(\Gamma, M : b)$ factors t . In other words, the following diagram is an equaliser.

$$\begin{array}{ccccc}
& & & 1 & \\
& & \nearrow & & \searrow 0 \\
T\Gamma & \dashrightarrow & T(\Gamma, M : b) & & \mathbb{N} \\
& & \searrow & & \uparrow \\
& & & & |-|_M
\end{array}$$

The crucial lemma is the following.

Lemma 13. *For any $\Gamma = (M_1 : a_1, \dots, M_n : a_n)$, $t : Ka \rightarrow T\Gamma$, and $\sigma : \Gamma \rightarrow T\Delta$,*

$$|t[\sigma]| = |t| + \sum_i |t|_{M_i} \times |\sigma_i|$$

Corollary 3. *For any $t : Ka \rightarrow T(\Gamma, M : b)$, $\sigma : \Gamma \rightarrow T\Delta$, $f \in \text{hom}_{\mathcal{D}}(a, b)$, $u : Kb \rightarrow T\Delta$,*

$$\begin{aligned} |t[\sigma, u]| &\geq |t| + |u| \times |t|_M \\ |\mathcal{L}Kf[u]| &= |u| \end{aligned}$$

Corollary 4. *If there is a commuting square in $Kl_{\mathcal{D}+}$*

$$\begin{array}{ccc} Ka & \xrightarrow{t} & \Gamma, M : b \\ \mathcal{L}Kf \downarrow & & \downarrow \sigma, u \\ Kb & \xrightarrow{u} & \Delta \end{array}$$

then $t = M(g)$ for some g or $T\Gamma \hookrightarrow T(\Gamma, M : b)$ factors t .

Proof. Since $t[\sigma, u] = \mathcal{L}Kf[u]$, we have $|t[\sigma, u]| = |\mathcal{L}Kf[u]|$. Corollary 3 implies $|u| \geq |t| + |u| \times |t|_M$. Therefore, either $|t|_M = 0$ and we conclude by Lemma 12, either $|t|_M = 1$ and $|t| = 0$ and so t is $M(g)$ for some g .

7 Completeness

Each inductive rule presented so far provides an elementary step for the construction of coequalisers. We need to ensure that this set of rules allows to construct a coequaliser in a finite number of steps. To make the argument more straightforward, we slightly alter the splitting rules (1) and (4) by enforcing that the coproduct $A_1 + \dots + A_n$ of objects of \mathcal{D} is split into A_1 and $A_2 + \dots + A_n$.

The following two properties are then sufficient to ensure that applying rules eagerly eventually leads to a coequaliser:

- progress, i.e., there is always one rule that applies (Section (7.1));
- termination, i.e., there is no infinite sequence of rule applications (Section (7.2)).

7.1 Progress

Progress for the main unification phase means that given a coequalising diagram

$$\coprod_i Ka_i \xrightarrow[t]{u} \Gamma, \text{ there is always one rule that applies, in some sense that can}$$

be made precise for each rule, roughly meaning that Γ , t , and u are of the shape Γ' , t' and u' (up to isomorphism) when the conclusion of the rule is $\Gamma' \vdash t' = u' \Rightarrow \dots$, and all the side conditions in the premises are satisfied (as, for example, the only premise of (5)). Similar definitions are required for the pruning phase.

Proposition 1. *Given an input $\coprod_{i \in I} Ka \xrightarrow[u]{t} \Gamma$, there is one rule of the unification phase that applies. Given an input*

$$\begin{array}{c} \coprod_{i \in I} Ka_i \xrightarrow{\coprod_i \mathcal{L}Kf_i} \coprod_{i \in I} Kb_i \\ g \downarrow \\ X \end{array}$$

there is one rule in the pruning phase that applies.

7.2 Termination

Here we sketch a standard termination argument for pattern unification. Roughly, it consists in defining the size of an input and realising that it strictly decreases in the premises. This relies on the notion of the size $| \Gamma |$ of a context Γ (as an element of \mathcal{D}^+), which can be defined as its size as a finite family of elements of \mathcal{A} (see Remark 3). We extend this definition to the case where $\Gamma = \perp$, by taking $| \perp | = 0$.

We also need to define the size¹ $||t||$ of a term $t : Ka \rightarrow T\Gamma$ recursively by $||M(f)|| = 1$ and $||o(f; s)|| = 1 + ||f||$, where the size of a list of terms is the sum of the sizes of each term in the list.

First, we sketch the termination argument for the pruning phase, and then for the main unification phase.

Pruning phase We define the size of a judgment $\Gamma \vdash f :> g \Rightarrow u; \sigma \dashv \Delta$ to be $||f||$. It is straightforward to check that the sizes of the premises are strictly smaller than the size of the conclusion, for each recursive rule of the pruning phase.

Unification phase We define the size of a judgment $\Gamma \vdash t = u \Rightarrow \sigma \dashv \Delta$ to be the pair $(| \Gamma |, ||t|| + ||u||)$. The following lemma ensures that for each recursive rule of the unification phase, the sizes of the premises are strictly smaller (for the lexicographic order) than the size of the conclusion.

Lemma 14. *For any $t : Ka \rightarrow T\Gamma$ and $\sigma : \Gamma \rightarrow T\Delta$, if σ is a renaming, i.e., if $\sigma = \mathcal{L}\sigma'$ for some σ' , then $||t[\sigma]|| = ||t||$.*

Lemma 15. *If there is a finite derivation tree of $\Gamma \vdash t = u \Rightarrow \sigma \dashv \Delta$, then*

- $| \Gamma | \geq | \Delta |$
- if $| \Gamma | = | \Delta |$ and $\Delta \neq \perp$, then σ is a renaming.

The proof of the latter lemma relies on the following result.

Lemma 16. *If there is a finite derivation tree of $\Gamma \vdash f :> g \Rightarrow u; \sigma \dashv \Delta$ and $\Delta \neq \perp$, then $| \Gamma | = | \Delta |$ and σ is a renaming.*

¹ The difference with the size definition in Section 6 is that metavariables are not of empty size. This property ensures that no term is of empty size.

8 Applications

8.1 Linear syntax

Take $\mathcal{A} = \mathbb{N}$ to be the discrete category whose objects are natural numbers. Following Remark (1), a ground context $n \in \mathbb{N}$ specifies the exact number of free variables; a metavariable arity specifies the number of arguments. The linear λ -calculus can be specified by the endofunctor defined by $F(X)_n = y1 + \coprod_{p+q=n} X_p \times X_q + (n+1) \times X_{n+1}$ (see [5]).

8.2 Simply-typed second-order syntax

Let T be a set of simple types. Here we consider $\mathcal{A} = \mathbb{F}_m[T] \times T$, where $\mathbb{F}_m[T]$ is the category of finite families indexed by T and injections between them. Let us denote an object (Γ, τ) of \mathcal{A} by $\Gamma \vdash \tau$. Following Remark (1), a metavariable arity $\Gamma \vdash \tau$ specifies the list Γ of input types as well as the output type τ .

If T is the set of simply types for the λ -calculus, generated by a set of base types, then the syntax for simply-typed λ -calculus can be specified by a suitable endofunctor, see e.g. [1].

8.3 Intrinsic polymorphic syntax

We present intrinsic system F , following [2]. Let $S : \mathbb{F}_m \rightarrow \text{Set}$ mapping n to the set Sn of types for system F taking free type variables in $\{0, \dots, n-1\}$. Now, consider the category \mathcal{A} of contexts of the shape $n; \sigma_1, \dots, \sigma_p \vdash \tau$, where $\sigma_i, \tau \in Sn$. A morphism between $n, \Gamma \vdash \tau$ and $n', \Gamma' \vdash \tau'$ is a monomorphism $\sigma : n \rightarrow n'$ and renamings $\Gamma[\sigma] \rightarrow \Gamma'$ such that $\tau[\sigma] = \tau'$. More formally, \mathcal{A} is the op-lax colimit of $n \mapsto \mathbb{F}_m[Sn] \times Sn$. The intrinsic syntax of system F can then be defined by a suitable endofunctor, see [2]. Following Remark (1), a metavariable arity $n; \sigma_1, \dots, \sigma_p \vdash \tau$ specifies the number of type arguments, the list of input types, and the output type.
